# **SML Classification models**

## **Naïve Bayes**

• Based on Bayes Theorem, where c is the class and d is the instance to classify:

$$P(c|d) = \frac{P(c) * P(d|c)}{P(d)}$$

• Estimate the probability of observing attribute a and the prior probability P(c):

$$P(c|d) = \frac{P(c) * \prod_{a \in d} P(a|c)}{P(d)}$$

### Naïve Bayes

#### Mean and Variance with a batch of n samples

$$\hat{x} = \frac{1}{n} * \sum_{i=1}^{n} x_i$$

$$\hat{x} = \frac{1}{n} * \sum_{i=1}^{n} x_i$$

$$\sigma^2 = \frac{1}{n-1} * \sum_{i=1}^{n} (x_i - \hat{x})^2$$

#### Mean and Variance with a stream $x_1, ..., x_i, ..., x_n$

$$s_i = s_{i-1} + x_i$$

$$\hat{x}_i = \frac{s_i}{i}$$

$$s_i = s_{i-1} + x_i$$
  $q_i = q_{n-1} + x_i^2$   $\hat{x}_i = \frac{s_i}{i}$   $\sigma_i^2 = \frac{1}{i-1} * (q_i - \frac{s_i^2}{i})$

# K-Nearest Neighbours (KNN)

- The most common label of the k instances closer to a new instance determines its label
- The distance between instances is calculated (commonly) using the Euclidean Distance:

$$d(a,b) = \sqrt{\sum_{i=1}^{m} (a_i - b_i)^2}$$

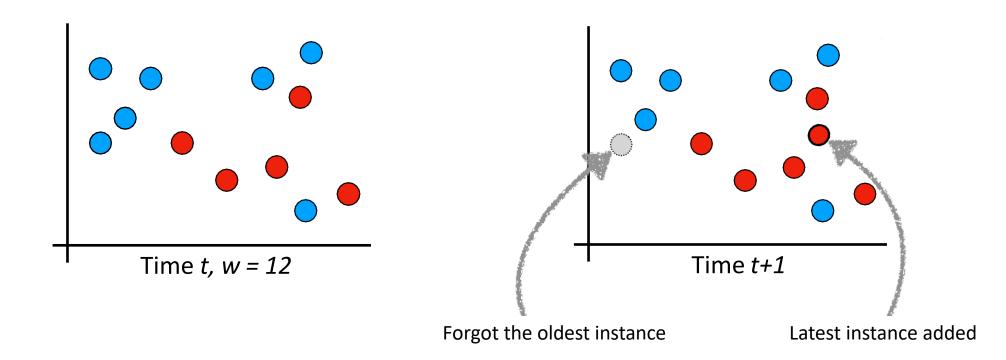

Bifet, A., Pfahringer, B., Read, J., & Holmes, G. Efficient data stream classification via probabilistic adaptive windows. ACM symposium on applied computing, 2013

# Online K-Nearest Neighbours (KNN)

Use a fixed size sliding window to save the instances

Bifet, A., Pfahringer, B., Read, J., & Holmes, G. Efficient data stream classification via probabilistic adaptive windows. ACM symposium on applied computing, 2013

# Online KNN with ADWIN (KNN-ADWIN)

- If a concept drift occurs, with KNN there is the risk that the instances saved into the window belong to the old concept
- Use ADWIN to automatically set the size of the sliding window to save the instances

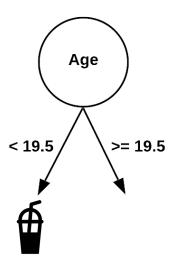

#### **Decision Trees**

#### **Recommending drinks**

Gender	Age	Drink
F	13	<b>f</b>
M	13	€
F	23	7
M	32	¥
F	42	7
M	16	<b>f</b>

#### Which feature best determines the drink?

12	<b>₫</b>
10	
12	ф
13	
23	<b>T</b>
32	¥
42	7
16	₩
	13 13 23 32 42

#### Which feature best determines the drink?

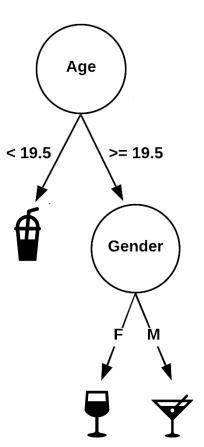

https://en.wikipedia.org/wiki/Decision\_tree\_learning

#### **Decision Trees**

- Each node tests a features
- Each branch represents a value
- Each leaf assigns a class
- Greedy recursive induction:
  - Sort all examples through tree
  - Xi = most discriminative attribute using the Gini index or Information Gain (H)
  - New node for Xi, new branch for each value, leaf assigns majority class
  - Stop if no error or limit on #instances

- Build the decision tree incrementally
- The final tree must be identical (with high probability) to a tree built using a batch decision tree algorithm
- With theoretical guarantees on the error rate

src: https://www.bilibili.tv/en/video/4787736782838275

- Which attribute to choose at each splitting node?
- A small sample can often be enough to choose the optimal splitting attribute
  - Collect sufficient statistics from a small set of examples
  - Estimate the merit of each attribute
- How large should be the sample?
  - Fixed size: defined a-priori without looking for the data

src: https://www.bilibili.tv/en/video/4787736782838275

- Which attribute to choose at each splitting node?
- A small sample can often be enough to choose the optimal splitting attribute
  - Collect sufficient statistics from a small set of examples
  - Estimate the merit of each attribute
- How large should be the sample?
- Fixed size: defined *a-priori* without looking for the data
- Moving size: Choose the sample size that allow to differentiate between the alternatives.

src: https://www.bilibili.tv/en/video/4787736782838275

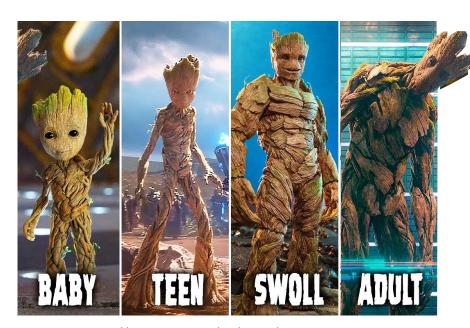

Pedro Domingos and Geoff Hulten. Mining high-speed data streams. 2000

- Moving size: Use Hoeffding bound to guarantee that the best attribute is really the best:
  - Let  $X_1$  and  $X_2$  be, respectively, the two most informative attribute

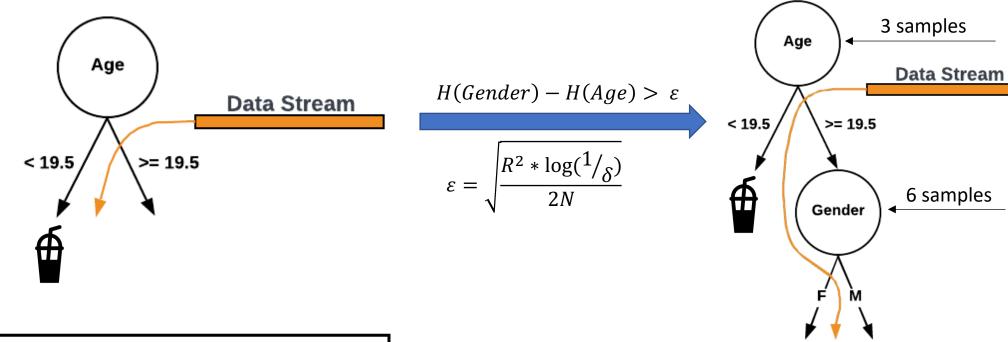

> Split if: 
$$H(x_1) - H(x_2) > \varepsilon = \sqrt{\frac{R^2 * \log(1/\delta)}{2N}}$$

where R is the H range,  $\delta$  is the confidence bound and N is the number of instances seen by that node

src: https://www.bilibili.tv/en/video/4787736782838275

**Attributes:** 

Label: Drink

- Age
- Gender

## **Concept Adapting VFDT (CVFDT)**

- What happens when a concept drift occurs?
  - The nodes are no longer representative of the current concept
- CVFDT keeps its model consistent with a sliding window of w samples
- It constructs "alternative branches" as preparation for changes
- If the alternative branch becomes more accurate, switch of tree branches

#### Cons:

- No theoretical guarantees on the error rate of CVFDT
- W is fixed

G. Hulten, L. Spencer, and P. Domingos. Mining time-changing data streams. 2001

# **Hoeffding Adaptive Tree (HAT)**

- Replace frequency statistics counters by estimators
  - Don't need a window to store examples, since it maintains the statistics data needed with estimators
- Change the way of checking the substitution of alternate subtrees, using a change detector with theoretical guarantees (ADWIN)
  - Keeps sliding window consistent with the no-change hypothesis

#### Pro:

- Theoretical guarantees
- No Parameters

A. Bifet, R. Gavald`a. Adaptive Parameter-free Learning from Evolving Data Streams. IDA, 2009

## **CASH problem and AutoML**

CASH problem: Combined Algorithm Selection and Hyperparameter.

AutoML aims to automate the data mining pipeline:

- Data cleaning
- Feature engineering
- Algorithm selection
- Hyperparameters tuning

Different implementations with different search spaces and hyperparameter optimizations:

- Auto Weka 2.0
- Autosklearn
- TPOT
- GAMA
- H2O

src: https://www.pexels.com/it-it/foto/radio-a-transistor-grigia-e-nera-157557/

## **CASH** problem with SML

CASH solution does not consider the adaptation of parameters in an evolving data stream.

Actual applications to a streaming scenario:

- Train AutoML only the first portion of the data stream
- Retrain AutoML from scratch after a concept drift
- Computational expensive
- Large number of parallel trainings
- Only consider algorithm selection

#### **EvoAutoML**

- It naturally adapts the population of algorithms and configurations
- It avoids expensive retraining
- It addresses the Online CASH problem by finding the joint algorithm combination and hyperparameter setting that minimizes a predefined loss over a stream of data

#### It considers:

- Pipeline structure
- Algorithms
- Configuration space
- It makes predictions by majority voting
